An integrated circuit comprises a large number of electronic components (e.g., transistors, diodes, rectifiers, and the like) that are fabricated together into a single substrate of semiconductor material. The substrate is formed into a final product by assembling and connecting the electronic components with leads to form finished circuits that function as designed. The final product functions as a device requiring precise electrical connections between each of its

electronic components. The present invention is in the field of integrated circuits. It concerns methods and system for making reliable connections in an integrated circuit. The invention is described in the context of microelectronic circuits, although it will be readily apparent that the invention may be applied to integrated circuits made in other materials, such as in integrated circuits made of silicon-on-insulator materials. A microelectronic circuit generally comprises a semiconductor substrate comprising the necessary components (e.g., transistors, diodes, and the like) to form one or more functional devices. In the context of this document, all such components are collectively

referred to as devices. The devices are usually made from a semiconductor material, such as silicon. However, the use of alternative semiconductor materials to silicon is also possible, such as germanium. In the fabrication process, a plurality of devices are formed in and/or on the semiconductor substrate. The various components of these devices require electrical connection to form an operable microelectronic circuit. Such connections may include, for example, bond pads, transistor gates and drains, vias, and other connections to the device. Typically, the connections to the device in the semiconductor substrate are made using a succession of metal layers, such as by a series of deposition, lithographic,

and etch steps. The final semiconductor product is formed by separating a die from the final semiconductor product by a process called "dicing". The dicing process is usually performed using a precise sawing machine. However, other techniques, such as laser scribing, are also known in the art. A problem in the art of microelectronic circuit connection relates to making reliable connections between microelectronic components. In the field of microelectronic circuit production, the quality of the connections between electronic components (which
